ABSTRACT

Awesome abstract that makes readers fall in love with the research and throw grant money at us in droves goes here. I'm going to just fill in some more words so we can get an idea of how much space our abstract will most likely take up. First we start by introducing ideas. Here are some ideas: compostable javelins with seeds in the points, which are somewhat hollow (or absorb water well) to allow for easy irrigation. These ideas come with problems. Now we'll mention that we're hoping to solve these by utilizing our LSS framework. Finally we'll discuss how the examples we've used have already shown clear advantages from using this process.

1. INTRODUCTION

A rational document driven design process for Scientific Computing (SC) software potentially improves the software qualities of verifiability, reliability, usability, maintainability, reusability and reproducibility [13]. However, many researchers have reported that a document driven process is not used by, nor suitable for, SC software; they argue that scientific developers naturally use an agile philosophy [1, 2, 4, 11] or an amethodical [6], or a knowledge acquisition driven [7], process. The arguments are that scientists do not view rigid, process-heavy approaches, favourably [2] and that in SC requirements are impossible to determine upfront [2, 12]. Rather than abandon the benefits of a rational document driven process, these arguments can be addressed

through the development of appropriate tools that support change and allow the scientist to focus on their science.

Our goal is to eat our cake and have it too. We want to improve the qualities (verifiability, reliability, usability etc.) of SC software and at the same time improve, or at least not diminish, performance. Moreover, we want to improve developer productivity to save time and money on SC software development, certification and re-certification. To accomplish this we need to remove (by hand generated) duplication between software artifacts for SC software [14] and provide complete traceability between all software artifacts. Practical accomplishment of these objectives means we need to provide facilities for automatic software artifact generation. We aim to accomplish this by having one “source” that captures all of the relevant knowledge for a given SC problem. From this source we can generate all required documents and views. That is, we aim to provide methods, tools and techniques to support a literate process for developing scientific software that generalizes the idea behind Knuth's [8] literate programming.

In the following sections we look at SC software, specifically focusing on software quality and literate programming. Then we introduce our framework for improving SC software development using a structured approach. We show a short example of the framework in action and discuss its advantages. We then discuss how we want the framework to evolve and what future work we intend to do. The last section provides concluding remarks.

2. BACKGROUND

In this section we discuss challenges for developing SC software and we introduce the ideas behind our approach.

2.1 Challenges for Scientific Computing Software Quality

The *technique selection challenge* [15] arises in SC because the best numerical approach to solve a given SC problem is not known a priori. Experimentation is inevitably necessary to answer questions such as the appropriate order of interpolation, the degree of implicitness, etc. For a framework for developing scientific software to be successful it should support a separation of concerns between the physical model and the numerical algorithm. Moreover, the framework should provide facilities for parameterizing the expected algorithmic variabilities for easy experimentation with different options.

The *understandability challenge* [15] comes up in the source code and in the final executable application. In an effort to

Permission to make digital or hard copies of all or part of this work for personal or classroom use is granted without fee provided that copies are not made or distributed for profit or commercial advantage and that copies bear this notice and the full citation on the first page. DOI: 10.475/123_4

make scientific libraries and software as widely applicable as possible most packages provide a generic interface with a large number of options. The number of options overwhelms users and causes programmers to not reuse libraries, since they do not believe the interface needs to be as complicated as it appears [3]. To improve understandability, an ideal framework will generate applications and libraries that are only as complicated as they need to be for the job at hand.

The *maintainability challenge* [15] tends to come up as requirements, especially for the physical model, change. As SC software is used at the forefront of scientific knowledge, there can be a high frequency of requirements changes. This causes problems for software that undergoes a process where it is certified as fit for use. If the expense and time required for re-certification is on the same order of magnitude as the original certification, changes will not be made. To be effective in this environment, a framework needs to provide traceability so the consequences of change can be evaluated.

2.2 Literate Programming

Literate programming (LP) is a programming methodology introduced by Knuth [8]. The main idea is to write programs in a way that explains (to humans) what we want the computer to do, as opposed to simply giving the computer instructions.

In a literate program, the documentation and code are together in one source. While developing a literate program, the algorithms used are broken down into small, understandable parts (known as “sections” [8] or “chunks” [5]) which are explained, documented, and implemented in an order which promotes understanding. To get working source code, the *tangle* process is run, which extracts the code from the literate document and reorders it into an appropriate structure for the computer to understand. Similarly, the *weave* process is run to extract and typeset the documentation. There are several examples of SC programs being written in LP style, such as VNODE-LP [9] and “Physically Based Rendering: From Theory to Implementation” [10] (a literate program which is also a textbook).

3. INTRODUCING LSS

Our framework, LSS, is being developed with the goals of providing complete traceability throughout the development process for SC software and reducing the amount of knowledge duplication across software artifacts. Both of these goals can be accomplished by following a (somewhat modified) literate approach.

3.1 The current state of LSS

LSS has been developed to this point using a practical, example-driven approach. The first example used in guiding the development of LSS involves the incredibly simplified Software Requirements Specification (SRS) for a fuel pin in a nuclear reactor (See Appendix A). It is a simple example, but the knowledge gained from it has been invaluable.

As of the time of this writing, we are able to generate much of the SRS for the fuel pin as well as the source code for the calculations contained within (See Appendix B).

3.2 How it works

The current framework is composed of several components including *chunks*, *recipes*, and a *generator*. The generator produces views of the source material, where these views are

Figure 1: The chunk hierarchy design

```

srsBody = Document ((S "SRS for ") :+
  (N $ h_g ^ . symbol) :+
  (S " and ") :+ (N $ h_c ^ . symbol))
  (S "Spencer Smith") [s1,s2]

s1 = Section (S "Table of Units")
  [s1_intro, s1_table]

s1_table = Table [S "Symbol", S "Description"] $ mkTable
  [(x -> Sy (x ^ . unit)),
   (x -> S (x ^ . descr))]
  s1_units

s1_intro = Paragraph (S "Throughout this ...
  
```

Figure 2: A portion of the SRS recipe

the software artifacts we require. Recipes are descriptions of these views and chunks contain the source material.

Each chunk needs to represent some concept, quantity, etc. Our current design introduces a chunk hierarchy (as seen in Figure 1), where the most basic chunk has only one field: a *name*. A “Concept” adds a *description*, and so on.

Each chunk is built from one or more of the existing chunks. This can be seen in the *h_c* definition in Figure 4. Thus, all of the information related to any one concept in a software project will be stored in a single chunk.

Recipes are specified using a micro- and macro-layout language embedded in Haskell. Each describes how the generated artifacts should appear: The micro-language handles the small-scale layout details (subscript and superscripts, concatenation of symbols, etc.), whereas the macro-language handles the larger layout details (sections, tables, etc.).

The source for our example has been broken down into the recipe, common knowledge, and specific knowledge. A portion of the recipe can be seen in Figure 2.

In this example, the fundamental SI units are common knowledge. Each is contained within its own chunk in the SI unit library. As Figure 3 shows, each chunk has a name, description, and symbolic representation.

The *h_c* chunk (Figure 4) is a piece of specific knowledge. It contains the name, description, symbol, units, and equation (written in an internal expression language) for *h_c*.

```

metre, kilogram, second, kelvin, mole :: FundUnit
metre = fund "Metre" "length (metre)" "m"
kilogram = fund "Kilogram" "mass (kilogram)" "kg"
second = fund "Second" "time (second)" "s"
kelvin = fund "Kelvin" "temperature (kelvin)" "K"
  
```

Figure 3: Segment of the SI unit library

```

h_c_eq :: Expr
h_c_eq = ((Int 2):(C k_c):(C h_b)) :/
  ((Int 2):(C k_c) :+ ((C tau_c):(C h_b)))

h_c :: EqChunk
h_c = EC (UC (VC "h_c"
  "convective heat transfer coefficient
  between clad and coolant"
  (sub h c) ) heat_transfer) h_c_eq

```

Figure 4: The h_c chunk

3.3 Advantages

We can already see the beginning of some advantages over traditional SC development. Certain advantages are relevant to specific challenges (Section 2.1) and will be explored further in the following sections.

3.3.1 Software Certification

High-quality documentation is required to certify software. The creation of said documentation should not impede scientists' work. One of the major problems in creating documentation for SC software stems from the maintainability challenge (Section 2.1). As requirements change, documentation must be updated. Changes to requirements result in greater changes to documentation as a project progresses. This creates issues with traceability and maintainability.

Depending on the regulatory body and set of standards for certification, many types of documents may be required. LSS aims to generate all of these documents alongside the code, while accounting for any changes. As the changes will affect chunks and those chunks will be used to generate the documentation and code, there is a guarantee that changes will propagate throughout all of the artifacts.

The following are examples of software artifacts that we wish to generate (we assume software engineers will be familiar with most, if not all, of these):

1. Software Requirements Specification (SRS)
2. Verification and Validation (V&V) plan
3. Design Specification
4. Code
5. V&V Report

The artifacts listed above share non-trivial amounts of information, which is where traceability comes into play. To make any changes to the documentation, there must be some way to determine how a change will affect **all** of the artifacts. This is especially important for (re-) certification, as the documents and source must remain consistent.

In the context of re-certification, if a piece of software were developed using LSS and some changes needed to be made, updating the artifacts and submitting them for re-certification would be completely trivial. All documentation would be generated from the (newly modified) chunks, according to their existing recipes. Or in the case of new information being added, a new chunk would be created and the recipe slightly modified. During the implementation of our example, we have already seen how LSS allows us to make changes at trivial cost.

On another note, if a document standard were to be changed during the development cycle, it would not necessitate re-writing the entire document. All of the information in the chunks would remain intact, only the recipe would need to be changed to accommodate the new view.

3.3.2 Knowledge Capture

In SC software there are many commonly shared theorems and formulae across different applications. For example consider the conservation of thermal energy equation:

$$-\nabla \cdot \mathbf{q} + g = \rho C \frac{\partial T}{\partial t}$$

This equation is widely used in a variety of thermal analysis applications, with each solving a different problem, or modeling a different system. Many applications tend to reimplement this equation, as opposed to reusing it [?].

Our approach aims to build libraries of chunks that can be reused anywhere. Each library should contain common chunks relevant to a specific application domain (ex. thermal analysis) and each project should aim to reuse as much as possible during development.

From our example, a common source of reused knowledge is the Système International (SI) units (Figure 3). They are used in applications throughout all of SC, so why should they be redefined for each project? Once the knowledge has been captured, they can simply be reused wherever necessary. With LSS they can be reused across projects with minimal effort, allowing developers and scientists to spend their valuable time on more important things.

3.3.3 "Everything should be made as simple as possible, but not simpler." (Einstein quote)

Currently there exist many powerful, general commercial programs for solving problems using the finite element method. However, they are not often used to develop new "widgets" because of the cost and complexity of doing so [?]. Engineers often have to resort to building and testing prototypes, instead of performing simulations, due to a lack of tools that can assist with their exact set of problems.

Our approach will change that by ideally making prototyping trivial through generating source code suited to the needs of the engineers. Changes in specifications could be seen in the code in (essentially) real-time at trivial cost. For example, if an engineer were designing parts for strength, they could have a general stress analysis program. This program could be 3D or specialized for plane stress/strain, depending on which assumption would be most appropriate at the time. The program could even be customized to the parameterized shape of the part the engineer is interested in. The new program would also only expose the degrees of freedom necessary for the engineer to change (ex. material properties or specific dimensions of the part), making the simulation process simpler and safer.

LSS tackles this understandability challenge (Section 2.1) by allowing developers to build components which will provide exactly what is needed, no more and no less.

3.3.4 Verification

When it comes to verification, requirements documents typically include so-called "sanity" checks that can be reused throughout subsequent phases of development. For instance, a requirement could assume conservation of mass or constrain lengths to be always positive. The former would be

Table 1: Future knowledge to capture

Var	Constraints	Typical Value	Uncertainty
L	$L > 0$	1.5 m	10%
D	$D > 0$	0.412 m	10%
V_P	$V_P > 0$ (*)	0.05 m ³	10%
A_P	$A_P > 0$ (*)	1.2 m ²	10%
ρ_P	$\rho_P > 0$	1007 kg/m ³	10%

used to test the output and the latter to guard against invalid inputs.

With LSS, these sanity checks can be ensured by the knowledge capture mechanism. Each chunk can maintain its own sanity checks and incorporate them into the final system to ensure all inputs and outputs (including intermediaries) are valid.

Also, with LSS, complete traceability is achievable through the use of chunks provided the requisite knowledge can be appropriately encapsulated.

Finally, any mistakes that occur in the generated software artifacts will occur **everywhere**. Errors propagate through artifacts, and the artifacts will always be in sync with each other (and the source), making errors much easier to find and allowing for easier document verification.

4. FUTURE WORK

Currently the framework is still very small, producing only one document type (the SRS) and only one type of code (C code for calculations). We plan to expand LSS in several ways including, but not limited to:

1. Generate more artifact types.
2. Generate different document views.
3. Include more types of information in chunks (see Table4).
4. Auto-generate test cases using constraints and typical values. The constraints should determine error cases, and typical value ranges give warnings.
5. Continue to expand the tool by implementing larger example systems.

For the auto-generation of test cases, physical constraints will be seen as hard limits on values (ex. length must always be positive and a negative value would throw an error). Typical values, on the other hand, are “reasonable” values (ex. the length of a beam should be on the order of several metres, but theoretically it could be kilometres, thus the code will raise a warning instead of an error).

5. CONCLUDING REMARKS

The current standard of using agile approaches to SC software development leave many things to be desired. Documents tend to fall out of sync with the source with each iteration, and the amount of hand-duplicated information leads to errors affecting the quality of the software.

We have begun the creation of a framework to help ensure complete traceability between software artifacts in the development process, while attempting to inconvenience the developers as little as possible. Using our framework will hopefully lead to higher quality software at very little cost.
