## ABSTRACT

What if building *well-documented* software was not tedious and unrewarding? We are implementing a framework, Drasil, to greatly alleviate these issues. Here we document the design and development process of Drasil. We show, through a case study (GlassBR – for computing the safety of glass panes with respect to explosions), how Drasil can be used. While software like GlassBR is algorithmically straightforward, it is used in safety related applications, which makes its correctness quite important. For Drasil, the context we are most interested in is when correctness is established within the context of *software certification*.

Our principal means of producing documentation is through weaving together standardized knowledge, as captured in Drasil. We illustrate how this makes scientific software development more transparent, and increases reusability and reproducibility.

## CCS CONCEPTS

• **Applied computing** → *Document preparation*; Physical sciences and engineering; • **Software and its engineering** → *Source code generation*; *Software development techniques*; *Reusability*; *Automatic programming*; *Traceability*; • **Social and professional topics** → *Testing*, *certification* and *licensing*;

## KEYWORDS

scientific computing, software quality, software engineering, document driven design, code generation, software certification

## 1 INTRODUCTION

Every developer should strive for software of the highest possible quality, especially for safety-related applications, where incorrect software could cost lives. As scientists, we should be leading the community in developing high quality software; our duty is to ensure the reusability, reproducibility, and replicability of our work.

Our team is focused on improving the quality of Scientific Computing Software (SCS). We have chosen large, multi-year, multi-developer projects where quality is sufficiently important that *certification* may be sought. In this domain, the end users do much of the development. For these projects, we pay particular attention to improving the qualities of reusability, reproducibility, and certifiability.

The goal for software certification is to: “...systematically determine, based on the principles of science, engineering and measurement theory, whether a software product satisfies accepted, well-defined and measurable criteria” [6, p. 12]. We aim to streamline the certification process, by simplifying the creation of the requisite software artifacts (documentation and code) and by ensuring these artifacts are always consistent. Tracking down the source of any information contained in our artifacts should be trivially easy. This is rarely the case (currently), as documentation is often not a high priority.

Improved documentation is often considered too high a cost in terms of time and effort for SCS developers, particularly when dealing with rapid changes in requirements. However, it is an important aspect of improving overall software quality. Carver [3] observed that scientists do not view rigid process-heavy approaches favourably. Moreover, others have observed that SCS developers tend to dislike producing documentation [10, p. 373].

Previous work by Smith & Koothoor [12] found 27 errors in an existing safety-related software package (nuclear safety analysis software) when re-documenting the software using a rigorous approach. Had they attempted to certify the software, most, if not all, of these errors would have led to a failure.

Well-maintained documentation provides numerous advantages including:

- Improved software qualities:
  - Verifiability
  - Reusability
  - Reproducibility
- Other improvements (from Parnas [8]):
  - Easier reuse of old designs
  - Better communication about requirements
  - More useful design reviews

Developers are being made aware of the advantages of documentation [11]. Yet it can still be difficult to realize these advantages because documenting software is typically felt to be:

- Too time consuming,
- Too difficult to maintain,
- Not amenable to change,
- Too tied to the waterfall process, and
- Counterproductive when reporting on each stage of development [10].

There are also other issues with document-rich, certifiable software development. Namely the vast amount of knowledge duplication across software artifacts. Consider a simple piece of software with the following artifacts:

- Software Requirements Specification (SRS),
- Design Document,
- Source Code, and
- Tests.

Knowledge such as the functional requirements from the SRS is duplicated in both the source code and tests. That same knowledge appears in the design document as well, albeit in a different form.

Software certification typically requires many more artifacts than the four listed above. Much of the same knowledge, possibly in a variety of representation, will appear in the artifacts and will need to be maintained. Manually maintaining these is a lesson in tedium and the time could be better spent elsewhere, if it were easier to deal with automatically.

How can we enjoy the benefits of documentation, without the usually associated drudgery? Our proposed solution is *Drasil* – a framework that uses a knowledge-based approach to software development, as originally proposed in a position paper by Szymczak et al [15]. The goal of the approach is to capture scientific and documentation knowledge in a reusable way, then generate the source code and all other software artifacts (documentation, build files, tests, etc) by using recipes to weave this knowledge into coherent pieces.

Work on Drasil has continued steadily since the original position paper, as described below. We begin with a brief overview of the design of Drasil in Section 2, then describe the development process that has been adopted in Section 3. Following this, we show an example of Drasil in action (Section 4) and the results we have seen to date (Section 5). Finally, we lay out some of the work that still needs to be done (Section 6) before concluding.

Figure 1: Drasil chunk hierarchy

## 2 DESIGN OF DRASIL

Drasil’s design is based around three main components:

- (1) Knowledge capture mechanisms (*Chunks*)
- (2) Artifact generation language(s) (*Recipes*)
- (3) Knowledge-base (*Data.Drasil*)

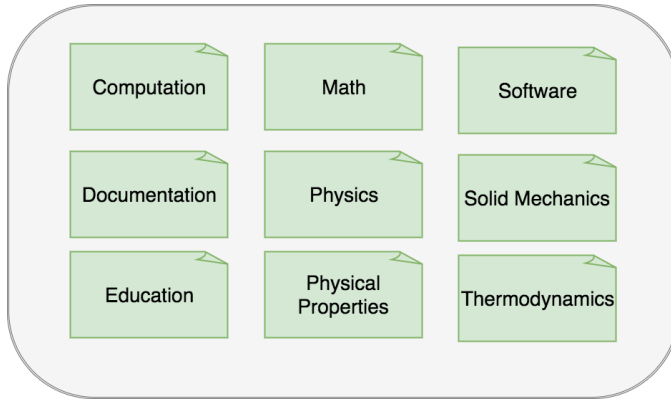

Chunks are the primary knowledge-capture mechanism. They come in many flavours (see Figure 1). The most basic chunk is simply a piece of data with an identifier (id). All other chunks inherit from this basic chunk. For example, a *NamedIdea* is a chunk containing an id, as well as a term which represents the idea and a potential abbreviation for that term; a *Quantity* is a *NamedIdea* which also has a *Space* (integer, boolean, vector, etc.), and symbol representation/units (if applicable). The notation in Figure 1 uses a +1 to indicate when a value may or may not be present (implemented using **Maybe** types in Haskell)). The id is an internal mechanism that allows us to build a database of chunks, and be able to look up information by id. It is not meant to be used externally.

We can think of chunks as our building blocks of knowledge; they are the ingredients to be used in our *Recipes*. Our language of recipes is a Domain-Specific Language (DSL) embedded in Haskell that is used to define what we would like to generate, and in what order. A small snippet of recipe language code for our Software Requirements Specification (SRS) can be seen in Figure 2. This code is used to generate the *Reference Materials* section of our SRS, which contains an introduction followed by the table of units, table of symbols, and table of abbreviations and acronyms subsections.

The document generation language is fairly abstract (it knows about sections, and subsections, various kinds of tables, and a variety of material typical of SRSes), and allows for a high degree of customization. Drasil also contains a code-generation language integrating GOOL [4] – a Generic Object-Oriented Language – which can generate code in a number of different target languages including Python, Lua, and C++. We will discuss code generation in more depth through the example in Section 4.

```
mkSRS :: DocDesc
mkSRS = [RefSec (RefProg intro
  [TUnits ,
   tsymb [TSPurpose , SymbOrder],
   TAandA]])
  ...
```

**Figure 2: The reference material section for an SRS written in Drasil’s Document Language**

**Figure 3: Data.Drasil knowledge domains**

Finally, there is the knowledge-base for Drasil (located in a series of modules in the Data.Drasil namespace). We are creating a database of reusable scientific knowledge that can be applied across a number of different applications across multiple domains. As the Drasil framework grows, we hope to continue to expand this database into an ontology of scientific knowledge for a number of disciplines. See Figure 3 for an example of some of the domains in which we have started to capture knowledge.

### 3 DEVELOPMENT PROCESS FOR DRASIL

We use an example-driven process – where the examples are all reimplementations of third-party software. This grounds our efforts, and ensures that we are able to reproduce real work rather than just toy examples. We currently use five different examples, which are being worked on concurrently, to drive the development of Drasil:

- Chipmunk2D Game Physics Engine
- Solar Water Heating System Incorporating Phase Change Material (PCM)
- Solar Water Heating System (No PCM)
- Slope Stability Analysis (SSP)
- Glass Breakage Analysis (GlassBR)

The original (non-Drasil) documentation for these examples came out of a study on Document Driven Design (DDD) for SCS [11].

Our approach allows us the flexibility to prototype without over-designing. As a new feature becomes necessary to continue the implementation of a given example, only then do we design, test, implement, and re-test it. We occasionally implement features we may need in the future, but only in those instances when it is obvious that we are taking the right approach. Five examples are

enough to see “patterns” emerging in different examples, which drive further design.

The five examples have also shown themselves to be an ideal means to bring additional members on to the project. Summer student research assistants joined the project and were responsible for completing most of the work on translating the original examples into Drasil, and then later transforming the examples, as the Drasil DSLs have been extended and refactored. Through their work, the students have demonstrated that using Drasil does not require prior knowledge of Haskell and code generation techniques. These students come from a variety of disciplines – Chemical Engineering, Applied Mathematics, Computer Science and Software Engineering, with levels of education ranging from first to third year of an undergraduate program. None of the students had prior knowledge of Haskell. Yet all picked up the ideas quickly, and were able to make very significant contributions. Most were already able to make contributions on their second day of work – and some were able to do substantial changes to the infrastructure too.

The current incarnation of the Drasil framework can be found on GitHub at <https://github.com/JacquesCarette/literate-scientific-software>. We use code peer-reviews throughout the development to correct missteps early on, and keep an up-to-date issue tracker for any bugs, feature requests, or other “to-do” tasks. This has been an invaluable means of communication, especially when various team members were travelling, or simply working asynchronously.

There are two means for prodding the development of Drasil: first, the usual “wouldn’t it be nice if we had feature X”. Second, and more importantly, a frequent *introspection* of the code, encoding of the examples, recipes, etc, to find patterns of use. This has led to many refactorings. But it has also led us to *de-embed* knowledge from recipes and examples into re-usable chunks. And of course, once patterns are found and abstracted, often this reveals new patterns.

By adopting a practical, example-driven, “bottom-up,” approach for the development of Drasil, we have avoided some of the problems inherent in a more theoretical, or “top-down,” approach. The size, scope and complexity of SCS means that attempting to imagine a priori the DSLs we would need would be exceedingly difficult. We would invariably leave something out and likely provide too simple a framework – or spend a huge amount of time designing features that turn out not to be needed in practice. Rather than try to arbitrarily determine the initial scope of Drasil, we let the examples tell us what they need. The “bottom-up” approach was previously successfully used for generating members of the family of Gaussian elimination algorithms [1], as well as a generator for geometry kernels [2].

The idea that scientific software forms a program family [14] is helpful for the current work. We can imagine that each of our five examples provides one specific instance of the more general family of SCS. With five examples we feel confident that enough of the commonalities and variabilities between members of the family of SCS are present that the initial implementation of Drasil will provide a reasonable starting point for implementing a representative subset of the full family of SCS.

Refname	DD:sdf.tol
Label	$J_{tol}$
Units	
Equation	$J_{tol} = \log \left( \log \left( \frac{1}{1-P_{tol}} \right) \frac{\left( \frac{a}{1000} \right)^{m-1}}{k \left( \frac{E \cdot 1000}{1000} \right)^2 \gamma^m * LDF} \right)$

Figure 4:  $J_{tol}$  from GlassBR Requirements

#### 4 A PRACTICAL EXAMPLE (GLASSBR)

GlassBR is software used by structural engineers to predict whether or not a slab of glass will be able to withstand a given explosion without breaking.

This software is fairly simple; it has two (structured) inputs, the glass geometry and blast type, and a tolerance (the allowed probability of breakage). The first two are comprised of a number of fields (glass type, dimensions, TNT equivalent factor, standoff distance, etc.).

The output of GlassBR is whether or not the glass slab is considered safe, determined by calculating the probability of breakage. This calculation involves interpolation from several tabulated values, as some of the quantities have as yet not well-accepted models beyond empirical interpolation from experiments.

We will follow one specific piece of knowledge through from requirements to code, as a means to illustrate the use of Drasil.

Let us start by taking a look at a data definition for the tolerable stress distribution factor ( $J_{tol}$ ) for GlassBR. Figure 4 shows  $J_{tol}$  as rendered by pdf<sub>latex</sub>, from the Drasil-generated  $\LaTeX$  that came from the  $J_{tol}$  quantity chunk. We can also generate the documents in HTML. The data definition is part of the requirements for the GlassBR software. As this requirement is in the form of a (solved) equation, it is straightforward to generate code to calculate  $J_{tol}$  from this. A python version of this code can be seen in Figure 5). From the  $J_{tol}$  quantity chunk, we can generate this code as well as the documentation! Not only that, but thanks to the incorporation of GOOL, we can also generate Java, Lua, C#, etc. We present the generated C# code for reference in Figure 6.

The source knowledge for generating both the documentation and the code has been captured using chunks, as shown in Figure 7. The value of  $J_{tol}$  is calculated from the `tolStrDisFac_eq` expression, which is part of the `tolStrDisFac` chunk. The equation (`tolStrDisFac_eq`) is defined using other quantity chunks, like `plate_len` and `mod_elas`. These chunks themselves have their own definitions, which includes their description, symbol and units. When the knowledge from  $J_{tol}$  is rendered in some form, the knowledge from its constituent chunks is also available. This means the *Description* field in Figure 4 can be generated automatically from the knowledge implicit in the `tolStrDisFac_eq` equation.

To facilitate potential future change, Figure 7 shows that the symbol for  $J_{tol}$  is defined as sub (`stressDistFac ^.` symbol) (Atomic "tol"). This means the symbol for  $J_{tol}$  is the symbol for the `stressDistFac` with the subscript "tol". If the symbol for `stressDistFac` should change from  $J$  to some other letter, the change in the base symbol and its variations will automatically be consistent throughout all artifacts.

During the process of translation from the original documentation [11] to the Drasil code, we noticed an error in the code and documentation. The formula for  $J_{tol}$  should not include the unit conversion implied by dividing by 1000 in a number of places. Luckily, with one quick change to `tolStrDisFac_eq` (shown in Figure 8), we have corrected the error in our knowledge-base. After re-running the generator, our code and documentation has now been fixed and remains consistent. With Drasil, we are able to correct an error in one place (in the knowledge-base) and every artifact that depends on that knowledge is automatically fixed.

Similarly to the knowledge for  $J_{tol}$ , we have captured all of the knowledge pertaining to GlassBR in chunks. Many of the chunks pertaining to documentation concepts were previously captured in our knowledge-base, under `Data.Drasil.Concepts.Documentation`, and are being reused in the GlassBR implementation. Figure 9 shows a number of these chunks. The chunks shown are all *NamedChunks*, an instance of the *NamedIdea* class, which have been constructed using other, smaller chunks of knowledge. In the case of `prpsOfDoc`, we have used a special combinator, 'of\_', for increased readability.

The knowledge used by GlassBR can be assembled and extracted in different ways to produce a multitude of views, i.e. our artifacts, including the SRS. For a sense of what we can generate from this knowledge, see the table of contents for the currently generated GlassBR SRS (Figure 10). The SRS template for GlassBR, and the other four examples, follows that from Smith and Lai [13], although a different recipe could be used to generate an alternate view of the requirements. For instance, the requirements documentation generated for some audiences could provide less detail on equation derivations. Again, our documents can be generated in TeX and/or HTML for more flexibility. Both contain automated internal referencing.

Another thing to note in our SRS is that the traceability information between definitions, assumptions, theories, and instance models is automatically generated, including the traceability graph shown in Figure 11.

### 5 QUALITY IMPROVEMENTS

Throughout Drasil's development lifecycle, we have already noticed a number of non-trivial quality improvements to the software examples being re-developed. These improvements come in a wide range of areas, but for the sake of brevity we will focus on certifiability, reusability, and reproducibility.

#### 5.1 Certifiability

Certifying (or re-certifying) software can be a lengthy and expensive process where a single error can cause the software to fail the certification process. Consider the following equation from our solar water heating example which states that energy in the water

```
def calc_j_tol(inparams):
    j_tol = math.log((math.log(1.0/(1.0 - inparams.pbtol))) *
        (((inparams.a / 1000.0) * (inparams.b / 1000.0)) ** (inparams.m - 1.0)) /
        ((inparams.k * (((inparams.E * 1000.0) *
        ((inparams.h / 1000.0) ** 2.0)) ** inparams.m)) * inparams.ldf)))
    return j_tol
```

Figure 5: Python code to Calculate  $J_{tol}$ 

```
public static double J_tol(InputParameters inParams, double h, double LDF) {
    return Math.Log((Math.Log(1 / (1 - inParams.P_btol))) *
        ((Math.Pow(inParams.a / 1000 * inParams.b / 1000, Constants.m - 1)) /
        (Constants.k * ((Math.Pow(Constants.E * 1000 * (Math.Pow(h, 2)), Constants.m)) * LDF))));
}
```

Figure 6: Generated C# code to Calculate  $J_{tol}$ 

```
stressDistFac = makeVC
    "stressDistFac" (nounPhraseSP $ "stress distribution" ++ " factor (Function)" ) cJ

sdf_tol = makeVC
    "sdf_tol" (nounPhraseSP $ "stress distribution factor (Function) based on Pbtol")
    (sub (stressDistFac ^. symbol) (Atomic "tol"))

tolStrDisFac_eq :: Expr
tolStrDisFac_eq = log (log (1 / (1 - C pb_tol)) * ((Grouping ((C plate_len / 1000) *
    (C plate_width) / 1000)) :^ (C sflawParamM - 1) / (C sflawParamK *
    (Grouping (Grouping (C mod_elas * 1000) *
    (square (Grouping (C act_thic) / 1000)))))) :^ (C sflawParamM) * (C loadDF))))

tolStrDisFac :: QDefinition
tolStrDisFac = mkDataDef sdf_tol tolStrDisFac_eq
```

Figure 7: Drasil (Haskell) code for  $J_{tol}$  Knowledge

```
tolStrDisFac_eq :: Expr
tolStrDisFac_eq = log (log (1 / (1 - C pb_tol)) * ((Grouping (C plate_len *
    C plate_width)) :^ (C sflawParamM - 1) / (C sflawParamK *
    (Grouping (C mod_elas * square (C act_thick))) :^ (C sflawParamM) * (C loadDF))))
```

Figure 8: Modified Drasil (Haskell) code for  $J_{tol}$  equation

must be conserved between the heating coil and water, and water and PCM (Phase Change Material):

$$E_W = \int_0^t h_C A_C (T_C - T_W(t)) dt - \int_0^t h_P A_P (T_W(t) - T_P(t)) dt$$

where:

- $E_W$  is the change in heat energy in the water
- $A_C$  is the heating coil surface area
- $A_P$  is the PCM surface area
- $h_C$  is the convective heat transfer coefficient between coil and water
- $h_P$  is the convective heat transfer coefficient between PCM and water

- $T_C$  is the temperature of the heating coil
- $T_P$  is the temperature of the PCM
- $T_W$  is the temperature of the water

This is trivial for a human to check, and writing code to automatically check it during the software execution is also very simple. However, it is still time-consuming and should it ever need to change, such as if there is a change in the assumption that the tank is a perfect insulator, it would require developers to make a number of modifications to many artifacts in the future.

Thanks to Drasil's knowledge-capture mechanisms, we can capture the above equation in one place, thus any changes can be made very quickly. Not only that, but sanity checks (such as ensuring constraints on inputs) can also be captured and reused. An example

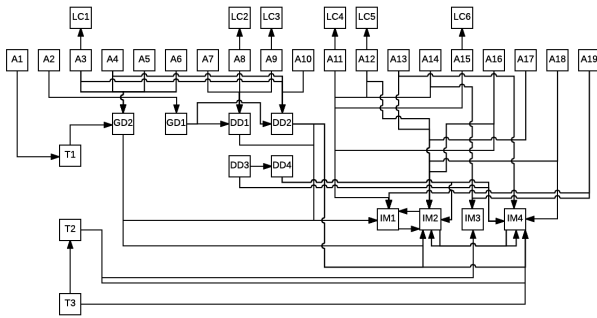

```

physicalConstraint = compoundNC physical constraint
physicalProperty  = compoundNC physical property
physicalSystem    = compoundNC physical system
problemDescription = compoundNC problem description
productUC         = compoundNC product_ useCase
safetyReq         = compoundNC safety requirement_
softwareConstraint = compoundNC software constraint
...
prpsOfDoc = npnc "prpsOfDoc"
            (purpose 'of_' document)

```

**Figure 10: Table of Contents for Generated SRS for GlassBR****Figure 11: Traceability Graph****Table 1: Constraints on Quantities – Used To Verify Inputs**

Var	Constraints	Typical Value	Uncertainty
$L$	$L > 0$	1.5 m	10%
$\rho_P$	$\rho_P > 0$	1007 kg/m <sup>3</sup>	10%

of these sorts of sanity checks can be seen in Table 1. They include hard physical constraints, ex.  $L > 0$ , as well as typical values. Capturing this information delivers a wider array of advantages, including:

- Generating guards against invalid input automatically
- Generating certain test cases automatically
- Generating views suitable for inspection
- Warning the user if they choose a value that is order(s) of magnitude different than the typical value

We can also see that it is straightforward to trace changes and verify that they are correct, thanks to our one-source, generative approach. We can produce documents similar to those commonly found in literate programming where we display the equations and code implementations (example: the  $J_{tol}$  equation and the python code used to calculate it) side-by-side, allowing a human to quickly verify the code is correct. This literate technique proved valuable with the nuclear safety analysis software mentioned earlier [12].

We have also touched on one of the greatest advantages (implied earlier): If there is an error somewhere, it is wrong everywhere.

This may seem like a disadvantage, but ensuring every artifact contains the same errors means there is a much greater chance of those errors being spotted. In our experience, many examples of software include code that does not match the design (due to hacks, last-minute changes, etc.), and an error that would hamper certification efforts can fly under the radar.

For (re-)certification purposes, we want to be able to find any and all errors, trace them to their source, and fix them quickly. Drasil has shown great promise in that respect.

## 5.2 Reusability

Reusability is a core tenet of Drasil’s development. This can be seen most obviously in the knowledge-capture mechanisms we have created. These mechanisms facilitate reuse through common knowledge databases for each domain (recall Figure 3). The reuse can occur within a single document, with a series of documents, and even between projects.

The value of reuse within a given document is seen in Figure 4 and Figure 10. Information on variables, including their definitions, their symbols and their units, is reused in multiple locations throughout the requirements document (SRS). For instance, lists of variables appear in the table of symbols, as part of each data definition and as part of the instance models. Maintaining the consistency between these different renderings would be very challenging manually, but by reusing the knowledge whenever necessary, the documentation is significantly more maintainable.

Consider the following software artifacts typically found in a rational design process for software development [9]:

- Software Requirements Specification (SRS)

- Module Interface Guide (MIS)
- Source Code
- Test cases

Within these artifacts, there is considerable duplication of specific knowledge related to the software being designed. Knowledge from the SRS will appear, possibly transformed, throughout each of the other artifacts. We seek to de-embed specific knowledge from within any one artifact to easily reuse it throughout them all. This knowledge includes, but is not limited to:

- Scientific Knowledge
- Models
- Units
- Symbols
- Descriptions
- Traceability information

While implementing our case studies in Drasil, we have found this de-embedding process to be invaluable. Previously “dead” information found in the software artifacts is now captured, reusable, and transformable. For example, an equation such as the one for defining  $J_{\text{tol}}$  can now be reused across artifacts in whatever form we deem necessary. This could be the equation written mathematically, described in English, or converted into executable code. Every form is still being generated from the same source, we simply reuse it in a slightly different way.

Reusing knowledge across artifacts in one software project is already incredibly useful, however, we have taken it a step further. Drasil allows us to reuse between projects. We can reuse a family of related models, or reuse pieces of knowledge from a given domain as necessary. Consider the vast number of software projects that rely on interpolation, or must ensure conservation of thermal energy. We can capture this knowledge once and reuse it through all of these projects.

We have already begun using knowledge across projects with great results. Our two implementations of the solar water heating systems (one with PCM and one without) have a vast amount of overlap in the requisite knowledge. The same governing equations, such as conservation of thermal energy, apply, but in a simplified form when one does not have to worry about heat transfer to and phase change of, the PCM. As such, these two implementation utilize many of the same chunks from our knowledge-base, simply reordered and transformed as necessary. If we find an error in the theory, or need to make a change to improve the validity of our calculations, fixing the Drasil source will update both projects (and any other members of the program family) simultaneously.

### 5.3 Reproducibility

Typically when we refer to reproducibility, the emphasis is on reproducing the calculations from compiled code. The problem is that over time programming languages, compilers and operating environments change. Virtual Machines (VMs) can be a significant help here, but VMs do not help when there are problems in the original code. What if our trust in the original code is in doubt? What if we need to reproduce the results not starting from the code, but starting from the original theory? Unfortunately, multiple examples exist [5, 7] where results from research software could not be independently reproduced, due to a need for local knowledge

missing from published documents. Examples of missing knowledge includes missing assumptions, derivations, and undocumented modifications to the code. Should it not be easier to independently replicate the work of others, without relying on the code they have written?

We want to replicate not only the execution of the code, but the whole of the software from theory to implementation. Given the appropriate theoretical knowledge, assumptions, equations, etc. we should be able to take this high-level knowledge and reproduce an implementation which will return consistent results. Drasil allows us to do exactly this; we can capture the high-level science knowledge and use it to reproduce a piece of software. We can also package our projects in a Drasil-ready format, such that the software can be generated on-the-fly by any who wish to replicate the results or double-check the science.

Drasil can also potentially check for completeness and consistency, ensuring the little things that are tedious, if trivial, to manually verify. For example: every symbol should be defined and used and should not change throughout the artifacts (inter- and intra-artifact consistency). This may seem minor, but one of our case studies, which had been reviewed by humans on numerous occasions, introduced a new symbol for an existing concept in a derivation. This new symbol was never defined and did not appear in the table of symbols. When implementing the project in Drasil, however, this error was made obvious almost immediately and was easily fixed.

Previously, the manual checks for verifying documentation have been listed [12]:

- check that every symbol is defined
- check that every symbol is used at least once
- check that every equation either has a derivation, or a citation to its source
- check that every general definition, data definition, and assumption is used by at least one other component of the document
- check that every line of code either traces back to a description of the numerical algorithm, to a data definition, to an instance model, to an assumption, or to a value from the auxiliary constants table in the SRS.

Going forward Drasil can be used to automate these checks and provide error or warning messages when they are violated.

Overall, Drasil lends itself incredibly well to ensuring reproducibility in a much larger sense than we normally consider. It allows us to focus on the science, (re-)building our projects from the fundamental knowledge instead of relying on a lone developer’s code. Drasil also forces all assumptions to be documented, and disallows local hacks, since the generated code should never be modified by a human, it should only be (re-)generated.

## 6 FUTURE WORK

Drasil has come a long way in the last year, yet there is still much to be done. With the current code-generation mechanisms being fairly naive, we have begun work on a language of design which allows us to apply design decisions to the theory knowledge to produce more flexible code. This language allows us to classify design and implementation choices in a reusable manner and will allow us

to progress with the generation of design documents, which are currently difficult to produce in Drasil.

The language of design will also facilitate more robust automated test case generation. By utilizing the captured design decisions, we will have a deeper knowledge of specific choices being made in our generated code. For example, in GlassBR, we will know which interpolation algorithm to use, and we will be able to generate test cases relevant to said algorithm.

Another large feature that will be a necessity in the long-run, but has thus far been relegated to the back-burner, is a much more user-friendly syntax, or even a tool to aid in the creation of Drasil projects. Drasil is currently fairly esoteric to use, even with all our documentation to date. Yet, with each iteration of the language we introduce new, simplifying abstractions, which have already made it easier to use. Our experience with our summer student research assistants is a testament to that. We are aware, however, of the gap that still needs to be closed before it will be ready for our target demographic.

We are also continuing work on:

- Generating new types of software artifacts
- Implementing much larger examples

Thanks to our practical approach to Drasil's design, there will likely be many other minor features to add and changes to make that are not yet entirely clear to us.

## 7 CONCLUDING REMARKS

While Drasil is still a work-in-progress, it shows great promise as a tool to aid SCS developers. The ability to capture scientific knowledge, document it, and transform it into usable code from a single, fully-traceable source should not be underestimated.

We have already seen non-trivial improvements to existing software during its re-implementation in our current, working-copy of Drasil. The case studies are now easier to verify, maintain, reuse, and replicate than they were before. There is also far less ambiguity on where certain concepts originated, as everything is captured in one source (the knowledge-base).

Not only do we believe that scientists will be able to create higher quality software while focusing more on the science; they will be able to replicate and reuse each other's work in a far more robust manner than we currently see in practice. We hope Drasil will solve the current problems with software result replicability starting from the theory [5, 7].

Software (re-)certification will also become a far less daunting task in a future with Drasil. With full traceability of information and the ability to generate new document views on-the-fly, we will be able to streamline the process. This means that recertification will be significantly less expensive than the original certification exercise.

While developing in Drasil does come with a fairly high, up-front investment of effort, we believe the long-term maintainability improvements, along with the streamlining of verification/certification and the other previously mentioned advantages are well worth the cost.

## ACKNOWLEDGMENTS

Drasil would not have progressed this quickly without the efforts of our summer research assistants: Henry Madej, Aaron Mori, Maryyam Niazi, Nicholas Richardson, and Daniel Scime.

The assistance of McMaster University's Dr. Manuel Campidelli, Dr. Wael El-Dakhakhni, and Dr. Michael Tait with the GlassBR example is greatly appreciated.
